Experiment No.6

Social Network Analysis using R (for example: Community Detection Algorithm)

Date of Performance:21/08/2023

Date of Submission:04/09/2023

Department of Computer Engineering

Aim: Social Network Analysis using R (for example: Community Detection Algorithm)

Theory:

Online social platforms have enabled people around the world to interact with each other and build relationships with others they share common interests with. This can be observed in real life — naturally, we tend to develop and maintain relationships with others that are similar to us. People with similar interests tend to gravitate towards each other and become associated in communities — clusters or groups of people that share similar traits with each other. Since people tend to cluster with others similar to them, we can use community detection to identify users with a high number of degrees (connections) and see how far their reach can travel in the network.

User Data Extraction — Since we are only interested in user data, we will only extract the following variables:

```
User_id — Yelp user ID; this is needed to make nodes and edges Name — user's first name
Review count — the number of reviews user has written
Yelping since — date user joined Yelp
Friends — a list containing all of the user's friends by user_id Fans — number of fans user has
Elite — number of years the user has Elite status
Average stars — user's average rating of all reviews written
```

CODE:

```
#remove users with no friends

sample <- subset(user_df, friends != "None")

#make a subset; we only need to retain data of users with some social activity

sub <- subset(sample, year == 2005 & review_count >= 2 & no_of_friends >=

2) #make links (nodes and edges)

sample_friends <- sub %>% select(user_id, friends)

sample_users <- strsplit(sample_friends$friends, split = ",")

sample_dat <- data.frame(user_id = rep(sample_friends$user_id, sapply(sample_users, length)), friends = unlist(sample_users))

#network is still too big, take a random sample of 100k nodes

samp_net <- sample_n(sample_dat, 100000)
```

Department of Computer Engineering

```
#make network
network <-
graph.data.frame(samp net) network s
<- simplify(network) net deg <-
degree(network s)
all degree <- degree(network, mode =
'all') #graph user with max degrees
sub_all <- subcomponent(network s, which(all degree == max(all degree)),
'all') g sub <- induced subgraph(network s, sub all)
#communities
graph.com <- fastgreedy.community(as.undirected(g sub))</pre>
V(g sub)$color <- graph.com$membership + 1
#create pdf graph for high resolution (try zooming
in!) pdf("communities2005.pdf", 10,10)
plot(g sub,
   vertex.color =
   V(g sub)$color, vertex.size =
   1,
   vertex.label = NA,
   vertex.frame.color = adjustcolor("#41424c", alpha.f = 0.25),
   edge.arrow.size = 0.1,
   edge.color = adjustcolor("#41424c", alpha.f =
   0.20), edge.width = 1.5,
   edge.arrow.mode=0,
   layout=layout with lgl,

CONCLUSION:

Our experiment delved into the realm of Social Network Analysis using R, with a specific focus on Community Detection Algorithms, unearthing significant findings regarding the structures of social networks. One key takeaway was the critical nature of algorithm selection, as performance can vary significantly based on the network's size and complexity. The inclusion of visual aids like network graphs greatly aids in interpretation. We also recognized the practical applications of Social Network Analysis in fields such as sociology, marketing, and epidemiology, where it sheds light on influential nodes and information diffusion. Future research avenues may explore more advanced algorithms and larger datasets. In essence, this experiment highlights the essential role of Social Network Analysis in comprehending intricate social relationships and its potential to bring benefits to various domains.
